

The Band-Edge Reversal Playbook

A checklist companion to the RRRK Reversal King charting tool. For medium traders who read charts daily and want a fixed vocabulary for what happens at long-horizon band edges.

Version 0.1 (demo phase) - Reversal King - reversalking project

How to use this playbook

This is a description manual, not a trading system. Every checklist inside converts the RRK engine's rules into questions you can ask of any chart, with or without the indicator loaded. Nothing here predicts, promises, or advises. The tool marks completed structures; you decide everything else.

Work through it in order: first the channel context (where the extremes sit), then the edge-event anatomy (what a rejection-with-reclaim bar requires), then the context lines that arbitrate trend health, and finally the study routine that turns all of it into a weekly habit.

The core principle: touch is not signal

Price touching a Donchian band means exactly one thing: price reached the highest high or lowest low of the last N bars. It is a location fact. The touch itself carries no information about direction, exhaustion, or continuation. RRK's markers exist only for the rarer event that follows some touches: a complete rejection-and-reclaim structure on a closed bar. Internalize this and half of all band-reading errors disappear.

Checklist A - Reading the channel context

Run before paying attention to any single bar.

[] 1. Note where price sits relative to the 1,400-bar channel: near upper edge, near lower edge, or mid-channel.

[] 2. Note how long since each band last extended. Fresh extremes and stale extremes describe different market characters.

[] 3. Classify the regime visible in the context lines: trending (lines stacked and sloped), ranging (flat and intertwined), or transition.

[] 4. Decide in advance which structures matter to you in this regime. Band-edge rejection reading has least meaning in dead ranges.

[] 5. Write down what the chart shows, not what you expect. The checklist exists to separate observation from hope.

Checklist B - Anatomy of a valid RS marker (upper edge)

All four must be true on the same closed bar. If any fails, no marker - and no setup under this definition.

[] 1. PRIOR BAR PRESSED THE EDGE: yesterday's high reached the channel top (within half a tick). No press, no setup.

[] 2. CURRENT BAR CLOSED BEARISH AND LOWER: red close, and below yesterday's close. Sellers took the session, not just visited it.

[] 3. CLOSE BEYOND THE PRIOR LOW: today closed under yesterday's low - the reclaim test. This is the strictest cut and eliminates most candidates.

[] 4. CONTEXT SAYS PULLBACK, NOT COLLAPSE: slow RMA(600) still below price, and medium RMA(400) still below the fast trend line.

RB at the lower edge is the exact mirror: prior bar presses the bottom, current bar closes bullish and higher, close beyond the prior high, same context test.

Checklist C - The context lines

What each plotted line contributes to the reading.

EMA 9 / 20	Short-term direction. Teal above red favors up-drift; red above teal favors down-drift.
h RMA(400)	The trend frame used by condition 4 of the marker logic. Price losing it changes the description from pullback to something else.
MA(600)	The deep anchor. Price holding above (or below) it keeps the larger frame intact regardless of short-term noise.
an bands	The multi-year extremes themselves. Location, not instruction.

What the tool shows - and what it does not

Where the true cycle extremes sit	Whether price will respect them
When a complete rejection-with-reclaim printed	What happens after the print
When RSI entered extreme zones (75 / 25)	That the extreme will reverse
Identical history on every user's chart	Any probability, target, or stop level

Checklist D - Weekly study routine

A repeatable review loop builds pattern literacy faster than screen-watching.

[] 1. Once a week, screenshot every new marker your watchlist produced. Archive them by date.

[] 2. For each marker, record which checklist items were visibly satisfied. Ambiguity in hindsight means ambiguity was present in real time too.

[] 3. Find one rejected candidate (press without reclaim) and one failed structure. Log why each stayed silent or broke its definition.

[] 4. Review band-walking episodes: trends that rode the edge with repeated shallow rejections. These are the recurring failure mode.

[] 5. Set TradingView alerts on the four signal conditions so review, not watching, is the workflow.

Failure modes to keep visible

- Band-walking: violent trends produce serial shallow rejections at the edge.
- Deep-pullback collapse: genuine reversals can begin exactly where pullbacks normally end; condition 4 will reject many of those bars by design.
- Range chop: flat, intertwined averages defeat both trend and reversal vocabulary.
- Definition drift: re-deciding rules after each outcome quietly destroys the framework's value.
